

Transforming the World

- Seeds changed the course of plant evolution, enabling their bearers to become the dominant producers in most terrestrial ecosystems
- Seed plants originated about 360 million years ago
- A **seed** consists of an embryo and nutrients surrounded by a protective coat
- Seeds can disperse over long distances by wind or other means

Concept 30.1: Seeds and pollen grains are key adaptations for life on land

- In addition to seeds, the following are common to all seed plants
 - Reduced gametophytes
 - Heterospory
 - Ovules
 - Pollen

© 2014 Pearson Education, Inc.

6

Advantages of Reduced Gametophytes

- The gametophytes of seed plants develop within the walls of spores that are retained within tissues of the parent sporophyte

12

Heterospory: The Rule Among Seed Plants

- The ancestors of seed plants were likely homosporous, while seed plants are heterosporous
- Megasporangia produce megaspores that give rise to female gametophytes
- Microsporangia produce microspores that give rise to male gametophytes

© 2014 Pearson Education, Inc.

13

Ovules and Production of Eggs

- An **ovule** consists of a megasporangium, megaspore, and one or more protective integuments
- Gymnosperm megasporangia have one integument
- Angiosperm megasporangia usually have two integuments

© 2014 Pearson Education, Inc.

14

Figure 30.3-1

© 2014 Pearson Education, Inc.

15

Figure 30.3-2

© 2014 Pearson Education, Inc.

16

Figure 30.3-3

Pollen and Production of Sperm

- Microspores develop into **pollen grains**, which contain the male gametophytes
- Pollination** is the transfer of pollen to the part of a seed plant containing the ovules
- Pollen eliminates the need for a film of water and can be dispersed great distances by air or animals
- If a pollen grain germinates, it gives rise to a pollen tube that discharges sperm into the female gametophyte within the ovule

The Evolutionary Advantage of Seeds

- A seed develops from the whole ovule
- A seed is a sporophyte embryo, along with its food supply, packaged in a protective coat

- Seeds provide some evolutionary advantages over spores
 - They may remain dormant for days to years, until conditions are favorable for germination
 - Seeds have a supply of stored food
 - They may be transported long distances by wind or animals

Concept 30.2: Gymnosperms bear "naked" seeds, typically on cones

- Gymnosperms means "naked seeds"
- The seeds are exposed on sporophylls that form cones
- Angiosperm seeds are found in fruits, which are mature ovaries
- Most gymnosperms are cone-bearing plants called **conifers**

Figure 30.1N02

The Life Cycle of a Pine

- Three key features of the gymnosperm life cycle are
 - Miniaturization of their gametophytes
 - Development of seeds from fertilized ovules
 - The transfer of sperm to ovules by pollen
- The life cycle of a pine provides an example

- The pine tree is the sporophyte and produces sporangia in male and female cones
 - Small cones produce microspores called pollen grains, each of which contains a male gametophyte
 - The familiar larger cones contain ovules, which produce megaspores that develop into female gametophytes
 - It takes nearly three years from cone production to mature seed

Figure 30.4

Figure 30.4a-1

Figure 30.4a-2

Figure 30.4a-3

Figure 30.4b-1

Figure 30.4b-2

Figure 30.4b-3

Animation: Pine Life Cycle

Early Seed Plants and the Rise of Gymnosperms

- Fossil evidence reveals that by the late Devonian period some plants had begun to acquire some features that are also present in seed plants
- For example, *Archaeopteris* was a heterosporous tree with a woody stem, but it did not bear seeds

33

© 2014 Pearson Education, Inc.

Figure 30.5

34

© 2014 Pearson Education, Inc.

- Living seed plants can be divided into two clades: gymnosperms and angiosperms
- Gymnosperms appear early in the fossil record about 305 million years ago and dominated Mesozoic (251–65.5 million years ago) terrestrial ecosystems
- Gymnosperms were better suited than nonvascular plants to drier conditions

35

© 2014 Pearson Education, Inc.

- Gymnosperms served as food for herbivorous dinosaurs
- Recent fossil discoveries show that gymnosperms were pollinated by insects over 100 million years ago
- Angiosperms began to replace gymnosperms near the end of the Mesozoic

36

© 2014 Pearson Education, Inc.

Figure 30.6

37

© 2014 Pearson Education, Inc.

Gymnosperm Diversity

- Angiosperms now dominate more terrestrial ecosystems, though conifers still dominate in some regions including the northern latitudes

38

© 2014 Pearson Education, Inc.

- The gymnosperms consist of four phyla
 - Cycadophyta (cycads)
 - Ginkgophyta (one living species: *Ginkgo biloba*)
 - Gnetophyta (three genera: *Gnetum*, *Ephedra*, *Welwitschia*)
 - Coniferophyta (conifers, such as pine, fir, and redwood)

39

© 2014 Pearson Education, Inc.

Phylum Cycadophyta

- Individuals have large cones and palmlike leaves
- Unlike most seed plants, cycads have flagellated sperm
- These thrived during the Mesozoic, but most of the few surviving species are endangered

40

© 2014 Pearson Education, Inc.

Figure 30.7a

Phylum Ginkgophyta

- This phylum consists of a single living species, *Ginkgo biloba*
- Like the cycads, this group also has flagellated sperm
- It has a high tolerance to air pollution and is a popular ornamental tree

Concept 30.3: The reproductive adaptations of angiosperms include flowers and fruits

- Angiosperms are seed plants with reproductive structures called flowers and fruits
- They are the most widespread and diverse of all plants

Figure 30.LN03

Characteristics of Angiosperms

- All angiosperms are classified in a single phylum, Anthophyta, from the Greek *anthos* for flower
- Angiosperms have two key adaptations
 - Flowers
 - Fruits

Flowers

- The **flower** is an angiosperm structure specialized for sexual reproduction
- Many species are pollinated by insects or animals, while some species are wind-pollinated

65

Video: Flower Blooming (Time Lapse)

69

- A flower is a specialized shoot with up to four types of modified leaves called floral organs:
 - **Sepals**, which enclose the flower
 - **Petals**, which are brightly colored and attract pollinators
 - **Stamens**, which produce pollen
 - **Carpels**, which produce ovules

66

Animation: Fruit Development

70

- A stamen consists of a stalk called a **filament**, with a sac called an **anther** where the pollen is produced
- A carpel consists of an **ovary** at the base and a **style** leading up to a **stigma**, where pollen is received

67

Figure 30.8

68

- Flowers that have all four organs are called **complete flowers**
- Those lacking one or more organs are called **incomplete flowers**

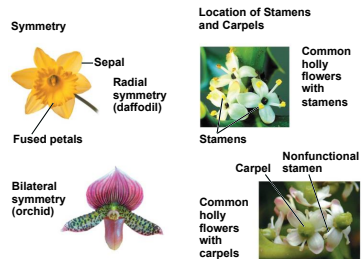

71

Symmetry

- Flowers may have **radial symmetry** or **bilateral symmetry**
- For flowers with radial symmetry, any imaginary line through the central axis divides the flower into two equal parts
- In bilateral symmetry, a flower can only be divided into two equal parts by a single imaginary line

72

Figure 30.9

73

Figure 30.9a

74

Figure 30.9b

75

Location of Stamens and Carpels

- Most species have flowers with both functional stamens and carpels, but in some species they occur on separate flowers
- Flowers with stamens may be on the same plant as those with carpels, or they may occur on different plants

76

Figure 30.9c

77

Figure 30.9d

78

Fruits

- A **fruit** is formed when the ovary wall thickens and matures
- Fruits protect seeds and aid in their dispersal
- Mature fruits can be either fleshy or dry

79

Figure 30.10

80

Figure 30.10a

85

© 2014 Pearson Education, Inc.

- Various fruit adaptations help disperse seeds
- Seeds can be carried by wind, water, or animals to new locations

86

92

© 2014 Pearson Education, Inc.

The Angiosperm Life Cycle

- The flower of the sporophyte is composed of both male and female structures
- Male gametophytes are contained within pollen grains produced by the microsporangia of anthers
- The female gametophyte, or **embryo sac**, develops within an ovule contained within an ovary at the base of a stigma
- Most flowers have mechanisms to ensure **cross-pollination** between flowers from different plants of the same species

93

© 2014 Pearson Education, Inc.

- A pollen grain that has landed on a stigma germinates and the pollen tube of the male gametophyte grows down to the ovary
- The ovule is entered by a pore called the **micropyle**
- Double fertilization** occurs when the pollen tube discharges two sperm into the female gametophyte within an ovule

94

© 2014 Pearson Education, Inc.

- One sperm fertilizes the egg, while the other combines with two nuclei in the central cell of the female gametophyte and initiates development of food-storing **endosperm**
- The triploid endosperm nourishes the developing embryo
- Within a seed, the embryo consists of a root and two seed leaves called **cotyledons**

Angiosperm Evolution

- Darwin called the origin of angiosperms an “abominable mystery”
- Progress is being made through the study of fossils and phylogenetic analysis, but the mystery of the sudden appearance of angiosperms has not been resolved

100

© 2014 Pearson Education, Inc.

Fossil Angiosperms

- Angiosperms originated at least 140 million years ago and began to dominate terrestrial ecosystems by 100 million years ago
- Chinese fossils of 125-million-year-old angiosperms share some traits with living angiosperms but lack others
- *Archaeofructus sinensis*, for example, has anthers and seeds but lacks petals and sepals

101

© 2014 Pearson Education, Inc.

Figure 30.13

Figure 30.13a

(a) *Archaeofructus sinensis*, a 125-million-year-old fossil

103

© 2014 Pearson Education, Inc.

Angiosperm Phylogeny

- The ancestors of angiosperms and gymnosperms diverged about 305 million years ago
- Angiosperms may be closely related to Bennettitales, extinct seed plants with flowerlike structures
- *Amborella* and water lilies are likely descended from two of the most ancient angiosperm lineages

104

© 2014 Pearson Education, Inc.

Figure 30.14

105

106

© 2014 Pearson Education, Inc.

Figure 30.14b

(b) Angiosperm phylogeny

107

© 2014 Pearson Education, Inc.

- Based on the features of ancestral and basal taxa, including *Amborella*, early angiosperms were likely small-flowered shrubs with simple water-conducting cells

108

© 2014 Pearson Education, Inc.

Evolutionary Links with Animals

- Animals influence the evolution of plants and vice versa
- For example, animal herbivory selects for plant defenses
- For example, interactions between pollinators and flowering plants select for mutually beneficial adaptations

109

© 2014 Pearson Education, Inc.

- Bilateral symmetry affects the movement of pollinators and reduces gene flow in diverging populations
- Plants with bilateral symmetry may have increased rates of speciation
- This hypothesis can be tested by comparing the number of species in closely related “bilateral” and “radial” clades

110

Figure 30.1UN04

Angiosperm Diversity

- Angiosperms comprise more than 250,000 living species
- Previously, angiosperms were divided into two main groups
 - Monocots (one cotyledon)
 - Dicots (two dicots)
- DNA studies suggest that dicots are paraphyletic

- The clade **eudicot** ("true" dicots) includes most dicots
- The rest of the former dicots form several small lineages
- Basal angiosperms** include the flowering plants belonging to the oldest lineages
- Magnoliids** share some traits with basal angiosperms but evolved later

Figure 30.16

Figure 30.16a

Figure 30.16b

Basal Angiosperms

- Three small lineages constitute the basal angiosperms
- These include *Amborella trichopoda*, water lilies, and star anise

Figure 30.17a

Star anise (*Illicium*)

Figure 30.17ac

Amborella trichopoda

Magnoliids

- Magnoliids include magnolias, laurels, and black pepper plants
- Magnoliids are more closely related to monocots and eudicots than basal angiosperms

Figure 30.17b

Magnoliids

Southern magnolia (*Magnolia grandiflora*)

Monocots

- More than one-quarter of angiosperm species are monocots
- The largest groups are the orchids, grasses, and palms

Concept 30.4: Human welfare depends on seed plants

- Seed plants are key sources of food, fuel, wood products, and medicine
- Our reliance on seed plants makes preservation of plant diversity critical

137

© 2014 Pearson Education, Inc.

Products from Seed Plants

- Most of our food comes from angiosperms
- Six crops (wheat, rice, maize, potatoes, cassava, and sweet potatoes) yield 80% of the calories consumed by humans
- Modern crops are products of relatively recent genetic change resulting from artificial selection
- Many seed plants provide wood
- Secondary compounds of seed plants are used in medicines

138

© 2014 Pearson Education, Inc.

Table 30.1

Table 30.1 Examples of Plant-Derived Medicines

| Compound | Source | Use |
|--------------|------------------|---------------------|
| Atropine | Belladonna plant | Eye pupil dilator |
| Digitalin | Foxglove | Heart medication |
| Menthol | Eucalyptus tree | Throat soother |
| Quinine | Cinchona tree | Malaria preventive |
| Taxol | Pacific yew | Ovarian cancer drug |
| Tubocurarine | Curare tree | Muscle relaxant |
| Vinblastine | Periwinkle | Leukemia drug |

139

© 2014 Pearson Education, Inc.

Threats to Plant Diversity

- Destruction of habitat is causing extinction of many plant species
- In the tropics 55,000 km² are cleared each year
- At this rate, the remaining tropical forests will be eliminated in 200 years
- Loss of forests reduces the absorption of atmospheric CO₂ that occurs during photosynthesis

140

© 2014 Pearson Education, Inc.

Figure 30.18

141

© 2014 Pearson Education, Inc.

Figure 30.18a

142

© 2014 Pearson Education, Inc.

Figure 30.18b

143

© 2014 Pearson Education, Inc.

- Loss of plant habitat is often accompanied by loss of the animal species that plants support
- At the current rate of habitat loss, 50% of Earth's species will become extinct within the next 100–200 years
- The tropical rain forests may contain undiscovered medicinal compounds
