

pGLO Bacterial Transformation

***Student presentation for use with
the pGLO Bacterial Transformation Kit***

Why genetically modify organisms?

- ***Disease/drought/pest resistance.***
- ***Increased nutrition***

- ***Modified animal models for research***
- ***Cancer, obesity, heart disease, etc.***

- ***Modified mosquitoes to fight disease***

- ***Drug production like insulin, hormones, vaccines, and anti-cancer drugs.***

Brief history of insulin

- 1922 – Canadian researchers isolate insulin, cure diabetics using bovine insulin, and win the Nobel Prize in 1923. Previously, diabetes had been a virtual death sentence – there was no treatment.
- 1978 – scientists at Genentech produce human insulin using genetically engineered E. coli (recombinant DNA, or rDNA).
- 1982 – Humulin approved by the FDA.

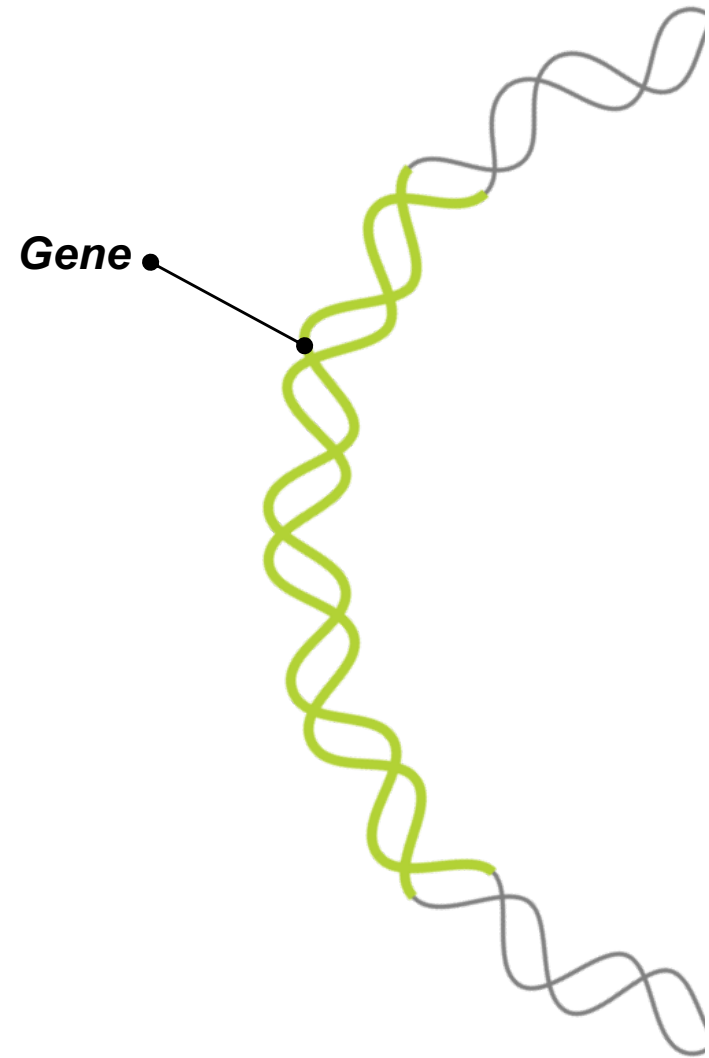

The protein products of biotech

	Used to treat	Made in	Price per gram
Gold	N/A	N/A	\$40
Insulin	Diabetes	<i>E. coli</i>	\$60
Human Growth Hormone	Growth disorders	<i>E. coli</i>	\$227,000
Granulocyte Colony Stimulating Factor	Cancers	<i>E. coli</i>	\$1,357,000

How can we make LOTS of protein?

1. Identify a gene for a protein.

How can we make LOTS of protein?

1. Identify a gene for a protein.
2. Put the gene into bacteria.

How can we make LOTS of protein?

1. Identify a gene for a protein.
2. Put the gene into bacteria.
3. Grow lots of the bacteria.

How can we make LOTS of protein?

1. Identify a gene for a protein.
2. Put the gene into bacteria.
3. Grow lots of the bacteria.
4. The bacteria transcribe and translate the gene — mini protein factories!

How can we make LOTS of protein?

1. Identify a gene for a protein.
2. Put the gene into bacteria.
3. Grow lots of the bacteria.
4. The bacteria transcribe and translate the gene — mini protein factories!

How can we make LOTS of protein?

1. Identify a gene for a protein.
2. Put the gene into bacteria.
3. Grow lots of the bacteria.
4. The bacteria transcribe and translate the gene — mini protein factories!
5. Purify the protein.

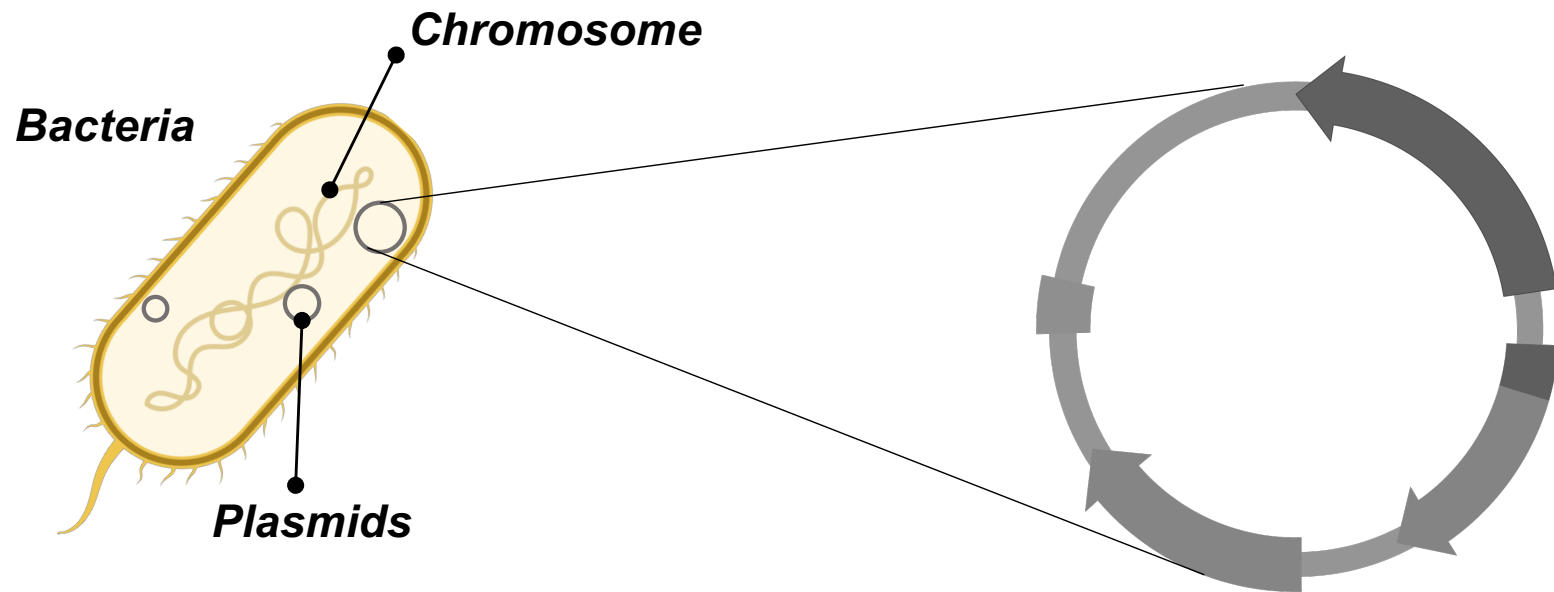

How do you get genes into bacteria?

1. Make a plasmid with your gene.
2. Do bacterial transformation. This is what you'll do in this activity.

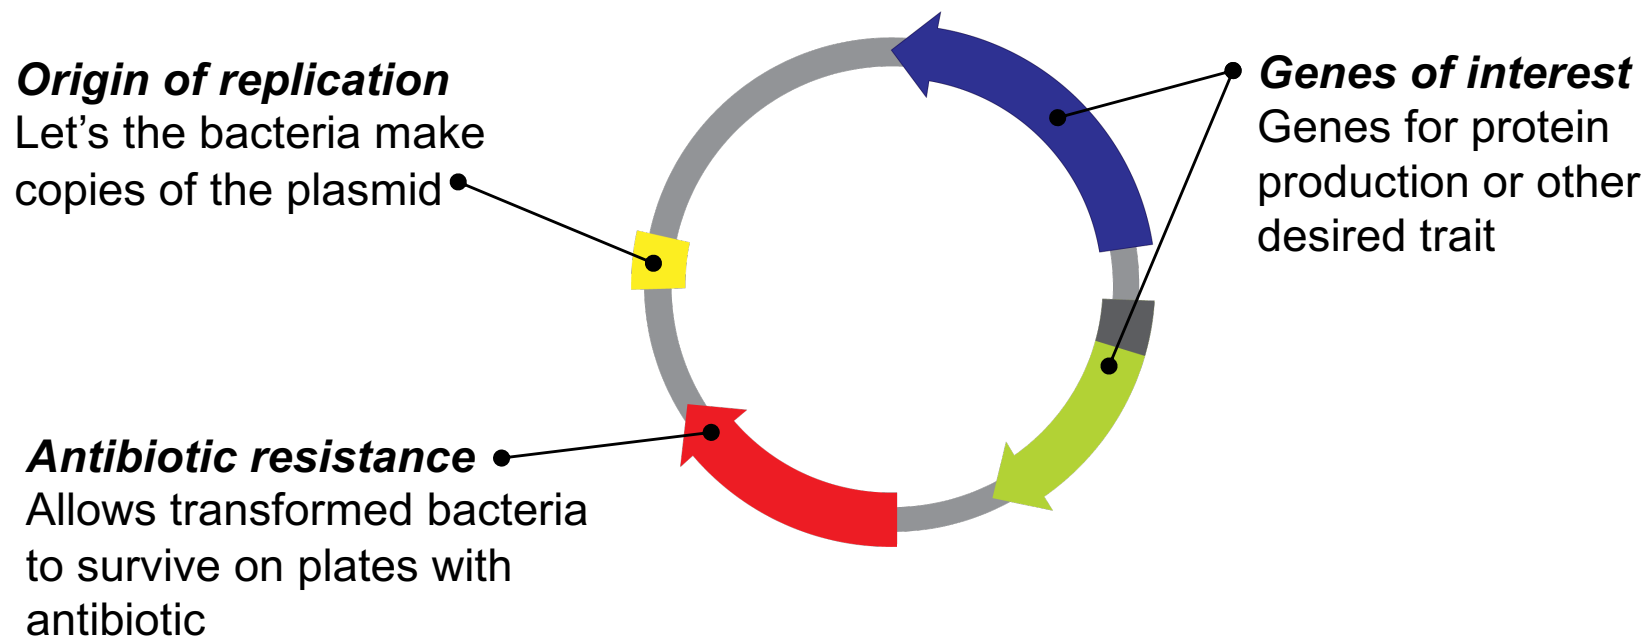

Genetic engineering using plasmids

- Bacteria often have plasmids — circular loops of DNA
- Bacteria can also take in new plasmids.

Genetic engineering using plasmids

- Scientists can modify or engineer plasmids for specific purposes.

Green fluorescent protein

Under visible light

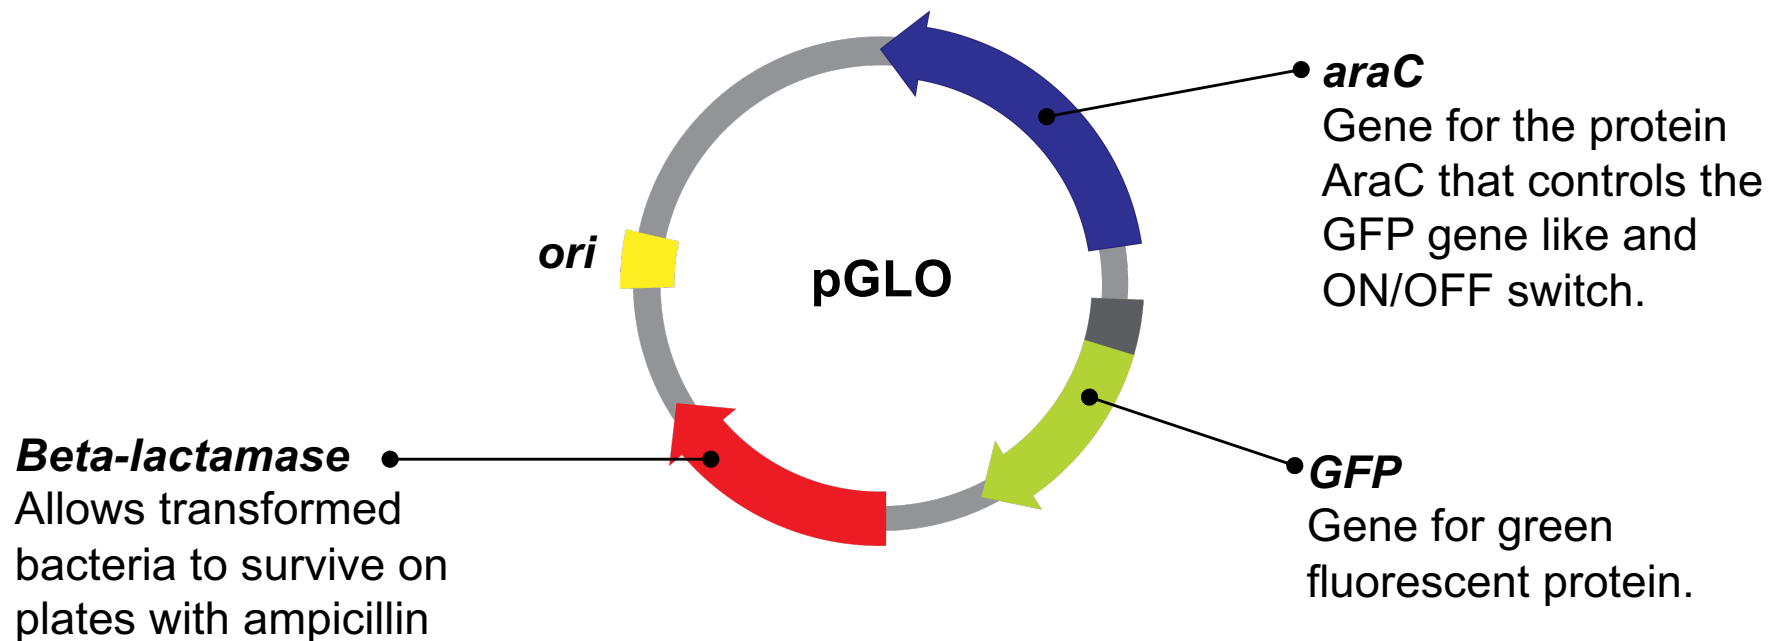

Under ultraviolet (UV) light

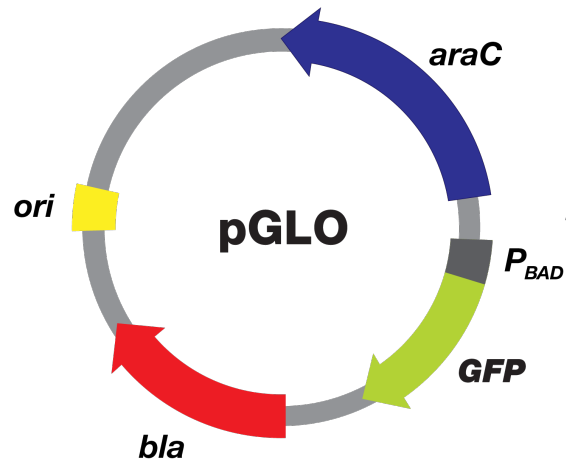

The jellyfish *Aequorea Victoria* has a gene for green fluorescent protein which glows green under UV light.

pGLO plasmid

- The pGLO plasmid is engineered to have the *GFP* gene from *Aequorea victoria*.

pGLO plasmid DNA

Bacterial Membrane

E. coli

Add plasmid

E. coli

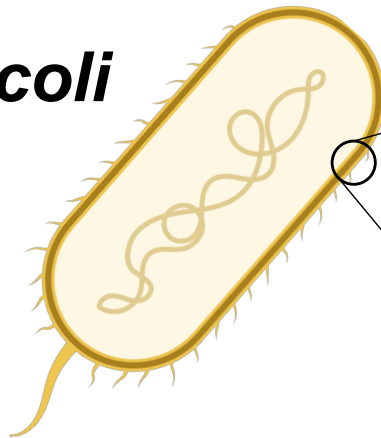

• *Plasmid DNA*

Plasma Membrane

Add plasmid

E. coli

*Negative charges
on DNA backbone*

Add transformation solution (CaCl_2)

Heat Shock

E. coli

*Add heat to
create pores in
the membrane*

Heat Shock

E. coli

*Add heat to
create pores in
the membrane*

Heat Shock

Recovery on ice, 2 min

E. coli

Add LB broth, allow gene expression, 10 min

Add LB broth, allow gene expression, 10 min

Selective media – ampicillin

Selective media – ampicillin

Selective media – ampicillin

Selective media – ampicillin

- Transformed bacteria (with the plasmid) will make beta-lactamase ■ , which breaks down ampicillin. This enables them to grow on ampicillin plates
- Bacteria without the plasmid (NOT transformed) cannot grow on plates with ampicillin.

LB Broth

- LB (Lysogeny broth or Luria Bertani) broth is like chicken noodle soup for bacteria. It has all the nutrients bacteria need to grow:
 - Carbohydrates
 - Amino acids
 - Nucleotides
 - Salts
 - Vitamins

Transformation summary

- | | | |
|----|--|--|
| 1. | CaCl ₂ transformation solution | Shields negative charge on DNA. |
| 2. | Pre-heat shock incubation on ice | Slows fluid plasma membrane for greater shock. |
| 3. | Heat shock | Increases permeability of cell membranes. |
| 4. | Post-heat shock incubation on ice | Restores cell membrane. |
| 5. | Incubation at room temperature with LB broth | Allows beta-lactamase expression so bacteria can grow on plates with ampicillin. |
| 6. | Spread on LB/amp plates | Selects for transformed bacteria and allows formation of colonies. |

Label tubes

You have tubes with 250 μ l transformation solution.

1. Label one **+pGLO** and the other **-pGLO**.
2. Add your initials.
3. Place into foam rack and on ice.

Pick colonies

4. **Using a sterile loop** pick 1–2 large *E. coli* colonies.
5. Add to the **+pGLO** tube. Spin the loop to disperse the bacteria. No clumps!
6. Using a **new** loop, at 1–2 colonies to **–pGLO** tube.
7. Place tubes into foam rack and on ice.

Add plasmid DNA

8. Add 10 μ l (1 loop full) pGLO plasmid to **+pGLO** tube.
DO NOT ADD TO -pGLO tube.
9. Place tubes into foam rack and on ice for 10 min.

Label plates

10. While your tubes are on ice, label the **bottom** of your plates.
11. Add your group ID or initials.

LB
-pGLO

LB/amp
-pGLO

LB/amp
+pGLO

LB/amp/ara
+pGLO

Heat shock

Get your timers ready!

12. Heat shock tubes at 42°C for exactly 50 sec.

13. **Immediately** return tubes to ice for 2 min.

14. Add 250 µl LB broth to both tubes.

15. Leave at room temperature for 10 min.

Meanwhile...

E. coli

Plasmid genes are expressed

Beta-lactamase

Beta-lactamase makes *E. coli* resistant to ampicillin

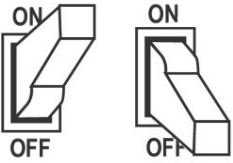

- Transformed bacteria (with the plasmid) will make beta-lactamase  , which breaks down ampicillin  . This enables them to grow on ampicillin plates
- Bacteria without the plasmid (NOT transformed) cannot grow on plates with ampicillin.

AraC

AraC Controls Expression of GFP

- Arabinose  (a sugar) works like a switch. 
- **Without** arabinose, the switch is OFF. AraC  blocks RNA polymerase  , and the GFP gene is not transcribed.
- **With** arabinose  , the switch is ON. AraC changes shape and RNA transcribes the *GFP* gene.

Green Fluorescent Protein (GFP)

Plating Bacteria

16. Flick tubes to mix.
17. Using a new sterile pipet, add 100 μ l bacteria to appropriate plates (**+pGLO** or **-pGLO**).
18. Use a loop to spread bacteria evenly.
Use a new loop for each plate.
19. Incubate overnight at 37°C or for 2 days at room temperature.

		<i>Plates</i>			
		<i>-pGLO LB</i>	<i>-pGLO LB/amp</i>	<i>+pGLO LB/amp</i>	<i>+pGLO LB/amp/ara</i>
<i>Components</i>	<i>Bacteria</i>				
	<i>DNA</i>				
	<i>Ampicillin</i>				
	<i>Arabinose</i>				
	<i>Grow?</i>				
	<i>Glow?</i>				

Transformation Efficiency

- How successful was your transformation?
You can calculate the transformation efficiency and compare with other groups.

$$\text{Transformation efficiency} = \frac{\text{Total number of colonies growing on the agar plate}}{\text{Amount of DNA spread on the agar plate (in } \mu\text{g)}}$$

Example $\frac{87 \text{ colonies growing on plate}}{0.16 \mu\text{g of DNA spread}} = 543 \text{ transformants}/\mu\text{g}$
(or 5.4×10^2 transformants/ μg)
